

Lab #8

EGRE246

1. Modify your lab #7 code to add the function `add` as defined below.

```
llist add(llist l, int n, int pos);  
// adds integer n to list l at position pos,  
// return this new list  
// where position 0 is the first item in list  
// -- if pos >=size of list, add n at end  
// -- if pos < 0, print warning message and do  
//    nothing (i.e. return l unaltered)
```

Remember you must consider the cases for both an empty and non-empty list `l`!

2. You of course must modify `main` to call and test this new function. Make sure you call it at least 6 times making sure to print the list each time to see it is correct; call it at least once to:
 - (a) pass in an empty list
 - (b) pass in a non-empty list inserting at position 0
 - (c) pass in a non-empty list inserting in middle
 - (d) pass in a non-empty list inserting at end
 - (e) calling it with position < 0
 - (f) calling it with position $>$ size of list
